## PREFACE

This report has been generated as part of a sub-contract between the Association of American Railroads Research and Test Department, and the University of Illinois.

This sub-contract is part of a larger contract which is a cooperative effort between the Federal Railroad Administration and the Association of American Railroads on improved track structures. The entire program is in response to recognition of the desire for a more durable track structure. To this end, the program is a multi-task effort involving 1) the development of empirical and analytical tools for the description of the track structure so that the economic trade-offs among track construction parameters such as tie size, rail size, ballast depth and cross section, type, subgrade type, stiffness, may be determined. 2) methodologies to upgrade the existing track structures to withstand new demands in loading, 3) development of performance specifications for track components, and 4) investigating the effects of various levels of maintenance.

This particular report describes a computer program for the finite element analysis of conventional railway track support systems.

A special note of thanks is given to Mr. William S. Autrey, Chief Engineer of Santa Fe, Mr. R. M. Brown, Chief Engineer of Union Pacific, Mr. F. L. Peckover, Engineer of Geotechnical Services, Canadian National Railway, Mr. C. E. Webb, Asst. Vice President, Southern Railway System, as they have served in the capacity of members of the Technical Review Committee for this Ballast and Foundation Materials Program, and Dr. R. M. McCafferty as the contracting Officer's Technical Representative of the FRA on the entire research program.

PART 1  
USER'S MANUAL

1.1 Introduction:

The finite element program was developed to evaluate the structural response of conventional railway track system, shown in Figure 1. The theoretical development of the finite element model is described in detail in Reference 1. A brief discussion of the modelling is given below.

The analysis is broken down into 2 stages. In the first stage, a longitudinal analysis is performed. Rail-tie representation is of the beam-spring type shown in Figure 2, which shows a typical finite element mesh used for longitudinal analysis. Wheel loads are input as point loads acting on the rail.

In the second stage, a transverse analysis is performed. The analysis considers a tie resting on the ballast. An option is included to consider the tie either as a two dimensional body or as a beam. A typical finite element mesh used for transverse analysis is shown in Figure 3. The maximum reaction or the maximum deflection at a tie obtained from the longitudinal analysis is used as input. Constant strain triangular elements can also be used to incorporate sloping ballast shoulder.

1.2 Modelling:

In each stage, a plane-strain type analysis is performed. The section to be analyzed is divided into a set of rectangular elements connected at their nodal points. Each node has two degrees of freedom: that for the beam-spring element are rotation and vertical displacement and that for the planar elements of ballast/subgrade system are horizontal and vertical displacements. The tie compression modulus for the longitudinal analysis is

(a) Longitudinal Section

(b) Transverse Section

Figure 1. A Typical Longitudinal and a Typical Transverse Section of a Conventional Railway Track Support System.

Figure 2. A Typical Finite Element Mesh Used for Longitudinal Analysis.

Note: Triangular elements can be used to incorporate sloping ballast shoulder.

Figure 3. A Typical Finite Element Mesh Used for Transverse Analysis.

converted into an equivalent spring constant. Presently, standard meshes are used, that for the longitudinal analysis being dependent on tie spacing and tie width. Typical element and nodal point numbering is shown in Figure 4.

A pseudo-plane strain state is considered for the ballast and the subgrade. The plane strain state generally distributes the load in two directions only and thus severely restricts the diminishing of the stress with depth as would be expected under the actual track system. In a pseudo-plane strain analysis, the finite element thickness is allowed to increase with depth to simulate 3 dimensional stress distribution with depth. The pseudo-plane strain state is shown in Figure 5.

### 1.3 Material Characterization

Granular and fine-grained materials exhibit, under repeated loading, strength characteristics that depend on the state of stress existing in the material. This response, termed the resilient response can be evaluated in the laboratory as follows:

- a. Ballast Material (Ref. 2), Figure 6

$$E_R = K_1 (\theta)^{K_2}$$

where:

$$E_R = \text{resilient modulus} = \frac{\text{repeated deviator stress}}{\text{elastic or recoverable strain}}$$

$$\theta = \text{sum of the principal stresses} = \sigma_1 + \sigma_2 + \sigma_3$$

$$= \sigma_1 + 2\sigma_3 \text{ in a triaxial test}$$

$K_1, K_2$  = constants determined from laboratory tests

- b. Fine-Grained Soils (Ref. 3)

Generally the resilient modulus of fine-grained soils decreases with an increase in deviator stress ( $\sigma_d = \sigma_1 - \sigma_3$ ). At higher values of

Figure 4. Typical Scheme for nodal and element numbering.

Figure 5. Pseudo-Plane Strain Approximation.

(No. 5 Gradation Limestone, High Density)

Figure 6. Typical Resilient Data for Ballast Material

deviatoric stress, the resilient modulus is almost constant. A typical resilient response curve for fine-grained soils is shown in Figure 7.

### c. Sandy Subgrades

The response for sandy subgrades is usually similar to that for granular materials and can be evaluated in the laboratory as follows:

$$E_R = K_1 (\theta)^{K_2}$$

The above type of material characterization is incorporated into the finite element program. Three types of non-linear analysis techniques can be used to incorporate stress-dependent material characterization. These techniques are:

1. Additive Incremental Loading. The load is divided into equal increments and at each step an increment of load is added to the previous step load. For example, in the first step only one increment of load is used and in the second step, two increments of load are used. Initial moduli values are assumed for the stress-dependent materials and are used to solve the problem with the first load increment. After the total load is applied, a single iterative analysis is carried out (with total load applied) so that the moduli values used in the final load increment are more compatible with the state of stress existing at the end of the final load increment.

2. Iterative Loading. The full load is applied for each iteration. Moduli values are assumed for the first iteration and the moduli values used for subsequent iterations are derived from the stress results of the preceding analysis.

3. Equal Incremental Loading. The load is divided into equal increments. Moduli values are assumed for analysis using the first load increment. Subsequently, the analysis is conducted using the same incremental

Figure 7. Typical Resilient Response Data for a Fine-Grained Soil (From Ref. 3).

load until the full load is applied. The deformations at the end of any increment are given by cumulatively adding the deformations of all the preceding load increments. The strains and stresses are then evaluated from the cumulative deformations.

Presently, only the load induced stresses are considered in the analysis and in calculating the bulk stress,  $\theta$ , for the granular materials, and the deviator stress,  $\sigma_d$ , for the subgrade soils.

#### 1.4 Failure Criteria

Failure criteria is incorporated in terms of:

1. minimum value of the minor principal stress,  $\sigma_3$ , for the granular materials, (tensile stress taken as negative),
2. maximum principal stress ratio,  $|\sigma_1/\sigma_3|$ , for the granular materials, and,
3. maximum shear stress  $(\sigma_1 - \sigma_3)/2$  for the subgrade soils.

This is a special case of Mohr - Coloumb failure condition for zero angle of internal friction.

#### 1.5 Boundary Conditions Used in the Longitudinal Analysis

In the present version of the longitudinal model, symmetrical loading is considered and only half of the system is analyzed. Loads are input as point loads acting on the rail at given distances from the center line of the section.

Due to loading symmetry, the nodes along the vertical boundary representing the centerline of the section to be analyzed are restrained from horizontal movement. Also, since horizontal deformation dissipates rapidly with distance from the loaded zone, a horizontal restraint on the other vertical boundary has been placed at a distance of 260 in. (6.6 m) from the center of the loaded area. The nodes along the bottom boundary, at a depth of about 300 in. (7.6 m), are restrained, both from horizontal

as well as vertical movement to simulate a rigid boundary. The above grid boundaries were chosen after several trial runs with different grid dimensions. The vertical external boundary and the bottom boundary will have some influence on the magnitude of the computed deflections but the influence would be small.

### 1.6 Boundary Conditions Used in the Transverse Analysis

Due to loading symmetry in the transverse direction, only half the transverse section is considered in the modeling and analysis. Loads are input as point loads and deflections are input as nodal deflections.

Again, due to loading symmetry, the nodes along the vertical boundary representing the centerline of the system are restrained from horizontal movement and as explained previously the other vertical boundary at a distance of 120 in. (3.1 m) is also restrained from horizontal movement. The nodes along the bottom boundary at a depth of about 300 in. (7.6 m) are restrained both from horizontal as well as vertical movement to simulate a rigid boundary.

### 1.7 General Logic of the Modelling

Relationships are established between generalized displacements (usually denoted as  $\{u\}$ ) and generalized forces (usually denoted as  $\{p\}$ ) applied at the nodes using the principle of virtual work or some other variational principle. This element force-displacement relationship is expressed in the form of element stiffness matrix (usually denoted as  $[k]$ ) which incorporates the material and geometrical properties of the element, viz.

$$[k] \{u\} = \{p\}$$

The overall structural stiffness matrix,  $[K]$  is then formulated by superimposing the effects of the individual element stiffness using the topological or the element connectivity properties of the structure. The overall stiffness matrix is used to solve the set of simultaneous equations of the form:

$$[K] \{U\} = \{P\}$$

where

$\{P\}$  = applied nodal forces for the whole system

$\{U\}$  = resulting nodal displacements for the whole system

The generalized stresses and strains are then calculated.

#### 1.8 Additional Program Guidelines

- 1) The Poisson's ratio for granular materials ranges from 0.30 to 0.40 and that for fine-grained soils ranges from 0.35 to 0.45.
- 2) The assumed initial moduli values can be evaluated as follows.
  - a) For the incremental loading techniques, the initial moduli values can be obtained as follows:  
Initially assumed moduli =  $\frac{\text{Expected final moduli}}{\text{Number of steps}}$
  - b) For the iterative loading technique, the initially assumed moduli value should equal the expected final moduli.
- 3) Presently it is suggested that the effective tie bearing length under each rail be equal to 18 in. (45.7 cm) and that the angle of distribution for pseudo-plane strain consideration,  $\phi$ , be equal to 10 degrees.

4) Low moduli values should be used when elements fail, i.e., satisfy failure criteria. Suggested failure moduli are 4000 psi (27579 kN/m<sup>2</sup>) for ballast and 100 psi (689 kN/m<sup>2</sup>) for subgrade.

5) Use of constant modulus value is suggested for stabilized layers. This can be incorporated as follows:

$$E_R = KONE (\theta)^{KTWO}$$

where KONE = constant modulus value to be used

$$KTWO = 0.0$$

6) The subgrade can be separated into an upper layer and a lower layer. The upper layer of the subgrade should not exceed 30 in. (76.2 cm). Different material characterization can then be used for the two subgrade layers.

### 1.9 General Flow Chart

1. Data input
2. Generate vertical and horizontal boundaries
3. Generate nodal point data and element connectivity data
4. Assign input data to individual element
5. For each incremental load step
  - a. Formulate the overall stiffness matrix
  - b. Solve for displacements
  - c. Calculate generalized stresses and strains
  - d. Calculate the element moduli corresponding to the existing state of stress
6. For final iterative step, do steps (5a) to (5c)
7. Stop

### 1.10 Sloping Ballast Shoulder

When a sloping ballast shoulder is to be incorporated into the transverse analysis, the following steps need to be carried out. The

transverse section grid nodes and elements should be numbered and the sloping shoulder should be drawn diagonally through the respective elements as shown in Figure 8(a). The elements containing the diagonal shoulder line should then be converted to constant strain triangular elements (see input data card types 8 and 17) and the rectangular elements above the sloping shoulder line would need to have their moduli value reduced to zero, i.e., constant moduli of zero (see input data card types 8 and 17), as shown in Figure 8(b). Also a node point belonging to the elements above the sloping shoulder line would need to be fixed in the vertical direction (see input data card types 14 and 18).

### 1.11 Data Requirements

#### a. Rail

1. Rail section moment of inertia ( $\text{in}^4$ )
2. Modulus of elasticity (psi)

#### b. Ties

1. Width, thickness and length (in)
2. Tie section moment of inertia (for transverse analysis - optional) ( $\text{in}^4$ )
3. Effective tie bearing length under each rail (in)
4. Modulus of elasticity (psi)
5. Poisson's ratio (for Transverse analysis)
6. Tie spacing (in)

#### c. Ballast or Subballast

1. Depth of ballast or subballast (in)
2. Initial modulus to be used (psi)
3. Resilient response model (psi)
4. Poisson's ratio
5. Failure criteria (psi)

(a) Transverse Section of CRTSS (Tie as beam).

Elements 152 and 168 changed to CST (triangular) elements  
 Element 167 changed to Type 10 element with zero modulus  
 Node 195 is fixed both horizontally and vertically

(b) Transverse section of CRTSS (Tie as beam) with sloping ballast shoulder.

Figure 8. Incorporation of Sloping Ballast Shoulder.

d. Subgrade

1. Total depth of section (including ballast/subballast) to be analyzed (in)
2. Depth of upper subgrade layer (if to be considered as a different material) (in)
3. For each subgrade layer
  - a. Initial modulus to be used (psi)
  - b. Resilient response curve data (psi)
  - c. Poisson's ratio
  - d. Failure criteria (psi)

e. Loading

1. Magnitude of point load (lb) or point deflection (in) and its distance from the centerline of the section to be analyzed. (Note: Since symmetrical loading is considered, only loading on one side of the centerline should be input).

1.12 Output:

The output given by the computer program is:

1. Rail moment and tie moment (at appropriate node points) (lbf in)
2. Rail deflection and tie deflection (at appropriate node points) (in)
3. Tie reaction (lb)
4. Stress patterns in the ballast, the subballast, and the subgrade (at centroid of appropriate elements)

$\sigma_{xx}$  (SIGXX) - horizontal stress (psi)

$\sigma_{yy}$  (SIGYY) - vertical stress (psi)

$\tau_{xy}$  (TAUXY) - shear stress (psi)

$\sigma_1$  (SIG1) - major principal stress (psi)

$\sigma_3$  (SIG3) - minor principal stress (psi)

5. Deflection and strain patterns in the ballast, the sub-ballast, and the subgrade (deflection at appropriate node points, strains at centroid of appropriate elements)

$\epsilon_x$ (EXXX) - horizontal strain

$\epsilon_y$ (EXYY) - vertical strain

$\gamma_{xy}$ (EXXY) - shear strain

### 1.13 Material Type

The material types used in the computer program are designated as follows:

|  | <u>Material Type</u> |
|--|----------------------|
| Ballast  | 1                    |
| Subballast   | 2                    |
| Lower (or the only) subgrade layer                                 | 3                    |
| Rail   | 4                    |
| Tie (as two-dimensional body)                                      | 5                    |
| Upper (if any) subgrade layer                                      | 6                    |
| Tie (as beam, for the length of tie)                               | 7                    |
| Tie (as beam, beyond the length of tie)                            | 8                    |
| Constant strain triangular element<br>for sloping ballast shoulder | 9                    |
| Constant modulus material for<br>rectangular elements only         | 10                   |

### 1.14 Present Usage

At present it is recommended that the "iterative loading" scheme be used for the "stress-dependent" analysis with failure criteria checked for at the end of the specified number of iterations (see data card Type 12). The final iteration is then carried out with the failure state incorporated into the analysis. Three iterations are sufficient to provide converging results.

## INPUT DATA STATEMENTS

The program can accept only fixed form type of format which is detailed below.

### Data Card Type 1

|       |  |
|-------|--|
| NPROB |  |
| 15    |  |

1                    5

NPROB = Number of separate problems to be solved.

The following input is repeated for NPROB times.

### Data Card Type 2

|           |           |           |            |
|-----------|-----------|-----------|------------|
| Title (1) | Title (2) | Title (3) | Title (20) |
| A4        | A4        | A4        | A4         |

1                    4 5                    8 9                    12                    76                    80

Title (1) to Title (20) = Title of individual problem

### Data Card Type 3

|        |        |  |
|--------|--------|--|
| ANAL   | ABCD   |  |
| F 10.2 | F 10.2 |  |

1                    10                    20

ANAL = Type of analysis

- = 1.0 for transverse analysis - tie as planar element
- = 2.0 for longitudinal analysis
- = 3.0 for transverse analysis - tie as beam element

ABCD = Type of non-linear (stress dependent) scheme to be used (See Sec 1.3)

- = 0.0 for additive incremental loading
- = 1.0 for full-load iterative loading
- = 2.0 for equal-step incremental loading

Data Card Type 4

| RLTIE  | WTIE   | TTHICK | BDEPTH | SBDEPT | TSPACE | BTHICK | PHI    |
|--------|--------|--------|--------|--------|--------|--------|--------|
| F 10.2 | F 10.2 | F 10.2 | F 10.2 | F 10.2 | F 10.2 | F 10.2 | F 10.2 |

1    10 11    20 21    30 31    40 41    50 51    60 61    70 71    80

RLTIE = Length of tie, in

WTIE = Width of tie, in.

TTHICK = Thickness of tie, in.

BDEPTH = Ballast depth, in.

SBDEPT = Subballast depth, in.

TSPACE = Tie spacing, in.

BTHICK = Effect bearing length of tie under each rail, for longitudinal analysis in.

PHI = Angle of distribution used for pseudo plane strain analysis (Presently 10.0 degrees is suggested)

Data Card Type 5

| DEPTH  | UPPER  | LCOL |
|--------|--------|------|
| F 10.2 | F 10.2 | 15   |

1    10 11    20 21    25

DEPTH = Total depth of section to be analyzed, in.

UPPER = Depth of upper (separate) layer of subgrade, in.

LCOL = Number of vertical boundaries to be used

= 0 for default condition, that is, when standard mesh is used.

Then for LCOL = 0

Number of vertical boundaries used = 13 for transverse analysis

= 27 for longitudinal analysis

Data Card Type 6

|         |        |        |         |        |        |  |

NPOINT = Numbers of points for the lower (or the only) subgrade layer resilient modulus curve data points = between 2 and 8 = 3 if NSUBL is 1.

JPOINT = Number of points for the upper (if any) subgrade layer resilient modulus curve data points = between 2 and 8, or 0 = 3 if NSUBU is 1.

NCST = Total number of elements to have either element type changed or to have constant modulus value. (See Sec 1.10) i.e., to Type (N) = 9.0 for CST element for sloping shoulder or Type (N) = 10.0 for constant modulus value element.

NSUBL = 0 if  $E_R$  vs  $\sigma_D$  relationship is used for the lower (or the only) subgrade.

= 1 if  $E_R = K(\theta)^n$  relationship is used for the lower (or the only) subgrade (e.g. for sandy subgrades)

NSUBU = 0 if  $E_R$  vs  $\sigma_D$  relationship is used for the upper  
 (if any) subgrade  
 = 1 if  $E_R = K(\theta)^n$  relationship is used for the upper  
 (if any) subgrade (e.g. for sandy subgrades)

Data Card Type 9

Lower (or the only) subgrade layer resilient modulus curve data points (NPOINT data cards)

|         |        |                            |
|---------|--------|----------------------------|
| RMOD(1) | DEV(1) | No. of data cards = NPOINT |
| F 10.2  | F 10.2 |                            |

1      10 11                      20

RMOD(1) = Resilient modulus value for the 1th data points, psi

UDEV(1) = Deviatoric Stress ( $\sigma_1 - \sigma_3$ ) value for the 1th data point, psi (1 goes from 1 to NPOINT)

If NSUBL = 1, the following resilient modulus relationship is used (e.g. for sandy subgrades):

$$E_R = BONE(\theta)^{BTWO} \quad (\text{units-psi})$$

Then,

RMOD(1) = BONE = Constant obtained from laboratory testing

DEV(1) = BTWO = Constant obtained from laboratory testing

RMOD(2) = Marker for failure criteria usage

= 0.0 if failure criteria is to be used (normal case)

= 1.0 if failure criteria is to be used in the final step (cycle) only

= 2.0 if failure criteria is not to be used

RMOD(3) = AMXSR

= Maximum allowable stress ratio,  $\sigma_1/\sigma_3$  for the sandy subgrade, psi

DEV(3) = SIGMN

= Minimum allowable principal stress,  $\sigma_3$  for  
the sandy subgrade, psi

Data Card Type 10

(If JPOINT not equal to zero) Upper (if any) subgrade layer resilient  
modulus curve data points (JPOINT data cards).

|         |         |                            |
|---------|---------|----------------------------|
| UMOD(1) | UDEV(1) | No. of data cards = JPOINT |
| F 10.2  | F 10.2  |                            |

1            10 11                                    20

UMOD(1) = Resilient modulus value for the 1th data point, psi

UDEV(1) = Deviatoric stress ( $\sigma_1/\sigma_3$ ) value for the 1th data point,  
psi (1 goes from 1 to JPOINT)

If NSUBU = 1, the following resilient modulus relationship is used  
(e.g. for sandy subgrades):

$$E_R = BONE(\theta)^{BTWO} \text{ (units-psi)}$$

Then,

UMOD(1) = BONE = Constant obtained from laboratory testing

UDEV(1) = BTWO = Constant obtained from laboratory testing.

UMOD(2) = Marker for failure criteria usage  
= 0.0 if failure criteria is to be used (normal case)  
= 1.0 if failure criteria is to be used in the final  
step (cycle) only  
= 2.0 if failure criteria is not to be used

UMOD(3) = AMXSR  
= Maximum allowable stress ratio,  $\sigma_1/\sigma_3$  for the  
sandy subgrade, psi

UDEV(3) = SIGMN

= Minimum allowable principal stress,  $\sigma_3$  for the sandy subgrade, psi

Data Card Type 11

|         |          |         |          |  |
|---------|----------|---------|----------|--|
| ETS (3) | PSRS (3) | ETS (6) | PSRS (6) |  |
| F 10.2  | F 10.2   | F 10.2  | F 10.2   |  |

1      10 11      20 21      30 31      40

ETS (3) = Initially assumed modulus for the lower (or the only) subgrade layer, psi

PSRS (3) = Poisson's ratio for the lower (or the only) subgrade layer

ETS (6) = Initially assumed modulus for the upper (if any) subgrade layer, psi

PSRS (6) = Poisson's ratio for the upper (if any) subgrade layer

Data Card Type 12

|        |        |        |         |        |        |        |        |
|--------|--------|--------|---------|--------|--------|--------|--------|
| AMXSRI | SIGMN1 | EFAIL1 | AMXSRI2 | SIGMN2 | EFAIL2 | BFLAG  | CFLAG  |
| F 10.2 | F 10.2 | F 10.2 | F 10.2  | F 10.2 | F 10.2 | F 10.2 | F 10.2 |

1      10 11      20 21      30 31      40 41      50 51      60 61      70 71      80

AMXSRI = Maximum allowable stress ratio,  $\sigma_1/\sigma_3$ , for ballast

SIGMN1 = Minimum allowable minimum principal stress,  $\sigma_3$ , for ballast, psi

EFAIL1 = Failure modulus for ballast, psi

AMXSRI2 = Maximum allowable stress ratio,  $\sigma_1/\sigma_3$ , for subballast

SIGMN2 = Minimum allowable minimum principal stress,  $\sigma_3$ , for subballast, psi

EFAIL2 = Failure modulus for subballast, psi

BFLAG = Marker for failure criteria usage of ballast  
= 0.0 if failure criteria is to be used  
= 1.0 if failure criteria is to be used in final step  
  
= 2.0 if failure criteria is not to be used

CFLAG = Marker for failure criteria usage of subballast  
= 0.0 if failure criteria is to be used  
= 0.1 if failure criteria is to be used in the final  
step  
= 2.0 if failure criteria is not to be used

Data Card Type 13

|        |        |        |        |  |
|--------|--------|--------|--------|--|
| TAUSUB | EFAIL3 | UTAUSB | EFAIL6 |  |
| F 10.2 | F 10.2 | F 10.2 | F 10.2 |  |

1      10 11      20 21      30 31              40

TAUSUB = Maximum allowable shear stress for the lower (or the only) subgrade layer, psi

EFAIL3 = Failure modulus for the lower (or the only) subgrade layer, psi

UTAUSB = Maximum allowable shear stress for the upper (if any) subgrade layer, psi

EFAIL6 = Failure modulus for the upper (if any) subgrade layer, psi

NOTE: the subgrade is assumed to be fine-grained soil and the minimum allowable shear stress would be given by half the unconfined compressive strength.

Data Card Type 14

|        |        |        |      |  |
|--------|--------|--------|------|--|
| NDSPEC | NFSPEC | NSTEPS | NFIX |  |
| 15     | 15     | 15     | 15   |  |

1            5 6            10 11            15 16            20

NDSPEC = Number of specified displacements in vertical direction only

NFSPEC = Number of specified loads in vertical direction only

NSTEPS = Number of incremental load steps

NFIX = Number of fixed degrees of freedom (displacements).  
 This is used to fix nodes a specified amount in a given direction. Used primarily when using CST elements (See Sec. 1.10)

Data Card Type 15 (if NFSPEC not equal to zero)

|          |         |                            |
|----------|---------|----------------------------|
| RLOAD(1) | DIST(1) | No. of data cards = NFSPEC |
| F 10.2   | F 10.2  |                            |

1            10 11            20

RDISP(1) = Magnitude of 1<sup>th</sup> point load (vertical), pounds

DIST(1) = Distance from center line of the 1<sup>th</sup> point load, in.

Data Card Type 16 (if NDSPEC not equal to zero)

|          |          |                            |
|----------|----------|----------------------------|
| RDISP(1) | DIST1(1) | No. of data cards = NDSPEC |
| F 10.2   | F 10.2   |                            |

1            10 11            20

RDISP(1) = Magnitude of 1<sup>th</sup> point displacement (vertical), in

DIST1(1) = Distance from center line of the 1<sup>th</sup> point displacement, in

Data Card Type 17 (if NCST not equal to zero)

| NECST | TYPE (NECST) | ETMM   | No. of data cards = NCST |
|-------|--------------|--------|--------------------------|
| 15    | F 10.2       | F 10.2 |                          |

1      5 6                      15 16                      25

NECST = Element number for the element to be modified  
(Type modification or constant modulus modification)

TYPE(NECST) = New type number of element (See Sec. 1.10)  
 = 9.0 for constant strain triangular element for ballast shoulder slope  
 = 10.0 if constant modulus is to be assigned to that element. (Element is then "linear")

ETMM = Constant modulus value to be used in the analysis  
 for TYPE (N) = 10.0 only.

Data Card Type 18 (if NFIX not equal to zero)

The set of NFIX cards are repeated (NSTEPS + 1) times

| M  | N  | TD(N, M) | No. of data cards = NFIX<br>Repeated (NSTEPS + 1) times |
|----|----|----------|---|
| 15 | 15 | F 10.2   |   |

1      5 6      10 11                      20

M = Node number whose displacement is to be fixed

N = Direction of displacement to be fixed  
 = 1 if horizontal displacement is to be fixed  
 = 2 if vertical displacement is to be fixed

TD(N, M) = Amount of displacement (normally equals 0.0)

If TD(N, M) is not equal to zero, then if ABDC = 0.0 (for additive incremental loading)

$$TD(N, M) = TD(N, M)_N \times \frac{N}{NSTEPS}$$

where  $TD(N, M)_N$  is the amount of displacement to be used in the  $N^{\text{th}}$  set of data cards and TD(N, M) is the total amount of displacement.

If ABCD = 2.0 (for equal-step incremental loading)

$$TD(N, M) = TD(N, M)_T / NSTEPS$$

where TD(N, M) is the amount of displacement to be used in all the NSTEPS set of data cards and  $TD(N, M)_T$  is the total amount of displacement.

PART 2  
TYPICAL EXAMPLES

Example 1:

Given:

A conventional railway track support system is comprised of the following.

Rail - 136 lb/yd (68 kg/m) rail

Moment of Inertia:  $I = 94.90 \text{ in}^4$  (3954  $\text{cm}^4$ )

Modulus of Elasticity:  $E = 30,000 \text{ ksi}$  (207,000  $\text{MN/m}^2$ )

Ties - Timber ties

Width = 8 in. (20.3 cm)

Thickness = 7 in. (17.8 cm)

Length = 8 ft (2.44 m)

Tie Spacing = 20 in. (50.8 cm)

Compressive Modulus = 1,250 ksi (8618  $\text{MN/m}^2$ )

Effective bearing length under each rail = 18 in. (45.7 cm)

Ballast - Crushed stone ballast, AREA #4 Gradation

Resilient Response Modulus:  $E_R = 5082 (\theta)^{0.58}$

Initial modulus used = 30,000 psi (207,000  $\text{kN/m}^2$ )

Poisson's ratio:  $\mu = 0.35$

Ballast Depth = 12 in. (30.5 cm)

Subballast - none

Subgrade (Embankment Material) - Depth = 275 in. (6.99 m)

$\mu = 0.47$

Resilient Response Curve Data: (Average Subgrade)

| $\sigma_D$ , psi (kN/m <sup>2</sup> ) | $E_R$ , psi (kN/m <sup>2</sup> ) |
|---------------------------------------|----------------------------------|
| 0.1 (0.7)                             | 14820.0 (102180.0)               |
| 6.2 (42.8)                            | 8000.0 (55160.0)                 |
| 36.2 (249.6)                          | 2900.0 (19990.0)                 |

Initial modulus used = 5,000 psi (34,500 kN/m<sup>2</sup>)

The following failure criteria is given:

- 1) Maximum stress ratio,  $\sigma_1/\sigma_3$ , for ballast = 10
- 2) Minimum compressive stress,  $\sigma_3$ , for ballast = 0 psi (0 kN/m<sup>2</sup>)
- 3) Maximum shear stress,  $(\sigma_1 - \sigma_3)/2$ , of subgrade = 25 psi (172 kN/m<sup>2</sup>)

(The failure criterion that tie springs cannot take tensile loads is incorporated in the computer program).

The loading to be used in the analysis consists of two trucks of two adjacent freight cars, each car having a gross weight of 240,000 lb (108800 kg), thus giving approximate wheel load of 30,000 lb (13600 kg). The truck spacing equals 150 in. (3.81 m) and the axle spacing equals 70 in. (1.78 m).

A longitudinal analysis is to be performed, using the angle of distribution for pseudo-plane strain analysis of 10° and the effective bearing length of tie of 18 in. (45.7 cm).

#### Example 2:

##### Given:

For the track support system given in Example 1 perform a transverse analysis at a "critical" tie. The maximum tie deflection (at the surface of the ballast) of 0.1025 in. (2.6 mm) obtained from the longitudinal analysis is to be used as input. Consider tie as a beam resting at the surface of the ballast.

Additional data required for the transverse analysis follows.

Tie

E = Compressive modulus = 1,250 ksi (8618 MN/m<sup>2</sup>)

I = 229.0 in<sup>4</sup>

TIEKK = Spring constant used in the transverse analysis  
considering tie as a beam = 999999 lbf/in./in.

Rail-tie intersections are 60 in. (1.52 m) apart.

(Note: Standard gage is 56 1/2 in. (1.44 m))

Computer Inputs for Examples 1 and 2:

(see following pages).
